

Cloud Migration & Modernization

Case study

A housing management platform with 150+ engineers completed a controlled cloud migration and modernization programme. Regression testing fell from three days to four hours, while incident resolution improved by 87.5%.

The challenge

Critical workloads ran across a fragmented hosting model. The organization needed to migrate without interrupting services for residents, property teams, service providers, or internal operations. Regression testing had become a three-day release event and operational context was distributed across systems.

Migration strategy

The programme began with workload discovery, dependency mapping, data-flow analysis, compliance review, recovery objectives, and migration-readiness scoring. Workloads were sequenced by business risk: low-risk components were rehosted first, selected services were replatformed, and high-value areas were modernized deliberately.

Cloud foundation

The target landing zone included network segmentation, identity and access guardrails, policy-as-code, centralized logging, backup, disaster recovery, cost controls, and clear ownership for every production service.

Execution and cutover

The teams created rehearsal environments, automated regression gates, migration runbooks, rollback criteria, observability dashboards, and a cutover plan with named decision owners. Data migration and application changes were tested in waves before production transition.

Outcomes

- Regression testing reduced from three days to four hours

- Incident resolution time reduced by 87.5%
- A controlled, observable cloud foundation
- A repeatable playbook for further migration and modernization
